AB PURPOSE: To compare the correlation between the departure areas (DA), negative or positive, in patients whose electrocardiogram showed left bundle branch block (LBBB) and association with left ventricular hipertrophy (LVH) and myocardial infarction (MI), to the electrocardiographic (ECG) and vectocardiographic (VCG) classic criteria. METHODS: The study was carried out with 46 patients (27 males) with LBBB. These patients had hypertension (19.5%), coronary heart disease (34.7%) and 21 patients with no heart disease (45.8%). RESULTS: The statistic analysis using the Cluster method divided the patients in two groups. Group I (22 patients) showed an average rate for the DA (-2 SD) of 1091 for QRS and of 640 for ST-T. For the DA (+2 SD), the average rate was 618 for QRS and 881 for ST-T; group II (24 patients) showed an averaged for the DA (-2 SD) of 1063 for QRS and of 225 for ST-T. For the DA (+2 SD), the averaged rate was 428 for QRS and 600 for ST-T. CONCLUSION: In general the current ECG/VCG findings, can not differentiate the presence of the association of LBBB to LVH and MI. The DA of ST-T, mainly negative was the most efficient to separate the two groups and help in the differential diagnosis.

 LA English  
 AB A solid phase immunoradiometric assay (IRMA) for quantification of bovine albumin fraction V (Bov.Alb.FV) in antileptospirosical Cuban vaccine vaxSpiral is described in the present work. Anti-Bov.Alb.FV IgG raised against rabbit purified by affinity chromatog. was used as first antibody. Anti-rabbit IgG labeled by Chloromine-T reaction was used as a tracer and the method has demonstrated to be sensitive with high intra- and inter-assay reproducibility. Eight lots of vaccinal antigens were evaluated and in all of the cases, the bovine albumin fraction V concentration was lower than 1 µg/mL, as the World Health Organization (WHO) establishes. This IRMA is a simple and sensitive assay and could be used as control method for all human vaccines that use Bov.Alb.FV in their production process, even cellular vaccines.

AB A vaccine effective against infection caused by group B Nesseria meningitidis microorganism is provided which comprises a purified protein antigenic complex weighing from 65 to 95 kDa, vesicles, and capsular polysaccharides. This vaccine is extracted from the cell membranes of the live microorganisms using detergent and enzyme. The method of producing an antimeningococcic hyperimmune gammaglobulin and the gammaglobulin produced by the method was provided. The gammaglobulin is obtained from vaccinees vaccinated with the vaccine.

AB A prospective epidemiological study was carried out over 1 year to evaluate vitamin B complex dietary intake and status in Cuba, 2 years after the Cuban neuropathy epidemic of 1993. Of the 199 healthy middle-aged men selected, 141 completed the study. Volunteers were followed up every 3 months for 1 year. Dietary intake and status of thiamin, riboflavin, vitamin B(6), folate and vitamin B(12) were assessed each time. The dietary intake of vitamin B complex was low, particularly in June and July (folate), and October (thiamin). A deficient status was observed for vitamin B complex, except for vitamin B(6). Vitamin B complex intake and status varied over the year. However, dietary intake and status were poorly related. The results prove that healthy Cuban men represents a vulnerable population in terms of vitamin B complex status and stress the necessity to both promote preventive multivitamin supplementation and produce local food rich in vitamin B complex.

AB To know the activity of antimeningococcal Ig, Balb/c mice of 18-22 g of body weight were challenged with 5 serotype B strains of Neisseria meningitidis (Nm) isolated from patients of different Latin American countries. The specific antimeningococcal Ig was extracted from the serum of volunteers previously vaccinated with the antimeningococcal BC vaccine VA-MENGOC-BC (Finlay Institute, Havana, Cuba). The Ig was i.p. (IP) administered in a unique dose of 10 mg/mouse. The strains A, B, C, CH and D were inoculated IP in the following charges: strain A, 20 LD50; B, 25 LD50; C, 44.5 LD50; CH, 36 LD50, and D, 200, 20 and 2 LD50. For each strain, a control group received living bacteria and virulent stimulating factor (VSF). The Ig was injected 30 min before or 30 min after the challenge dose had been given, except for strain D, which only received the Ig 30 min after the challenge. As VSF, 0.5 mg of iron in the form of iron dextran was used. The experiment was analyzed considering the survival time after the challenge for each strain compared to the corresponding control group (C). When the Ig was used 30 min before the challenge, the protection period for the A strain was (C:18.1h) more than 72h ( $P<0.001$ ) and 100% survival; for the B strain, (C:29.5h) 42h ( $P<0.05$ ) and almost 20% survival; for the C strain (C:16.5h) 35h ( $P<0.01$ ) with a 40% survival, and the CH strain (C:18.1h) 26.5h ( $P<0.02$ ), with a 20% survival. When the Ig was injected 30 min after the challenge, the average survival time and the survival for the A strain was 28h ( $P<0.05$ ) with 62.5%; for the B strain it was 42 h ( $P<0.005$ ) and 0.0%; for the C strain 27.3 h ( $P<0.05$ ) and 30%; for the CH strain 25.8h ( $P<0.05$ ) and 0.0%, and for the D strain 19.1h, 26h, and more than 72h with a 0.0%, 60% and 100%, depending on the challenging dose. In general, the specific Ig used showed a protective effect in mice against the different Latin American strains tested. Addnl., the exptl. model proved to be useful for the study of the antimeningococcal human Ig.

AB BACKGROUND: Multiple myeloma is rarely curable. Advances in high dose chemotherapy and stem cell transplantation have improved overall survival and event-free disease periods, but relapses are inevitable. AIM: To report our experience with AT in multiple myeloma, between 1994 and 2003. MATERIAL AND METHODS: Retrospective analysis of 20 patients (12 women), with a mean age of 51.1 years. VAD (vincristine, doxorubicin and dexamethasone) was used as initial therapy in 19 patients. High dose cyclophosphamide (11 patients) and variations of VAD regimen (7) associated with granulocyte colony stimulating factor were used for peripheral-blood stem cell harvest. The conditioning regimen consisted of melphalan 200 mg/m2 followed by the reinfusion of peripheral-blood stem cells 24 hours later. The median number of CD34 cells infused was  $3.3 \times 10^6$ /kg. Three patients were subjected to a second auto graft and one to a non-myeloablative transplant. Mean follow up was 35.5 months. RESULTS: Mucositis and febrile neutropenia were common complications. The median number of days for neutrophil engraftment was 9 (range 8-11) and for platelets, 10 (range 7-13). No patient died. Complete remission was

obtained in 60% (12/20), progression-free survival was 30 months and overall median survival, 47 months. CONCLUSIONS: The AT with high-dose melphalan is a safe procedure in our hospital, without mortality and engraftment in all the patients. Complete remission and progression free survival were similar to those reported abroad but the overall median survival was lower.

AB We report a 78 year old male with prostatism, that was subjected to a prostate biopsy. The pathological study showed a microvascular lymphocytic infiltration. Four months later, the patients presented with reduced alertness, cough, dyspnea, fever and elevation of lactic dehydrogenase and erythrocyte sedimentation rate. Chest and abdominal CAT scans, bone marrow aspirate, protein electrophoresis and prostate specific antigen were normal. A re-evaluation of prostate biopsy showed an intravascular lymphoid infiltration, positive for CD45 and CD20, compatible with the diagnosis of intravascular lymphoma. Chemotherapy was started, but it was not tolerated by the patient and the response was partial. Therefore, treatment with monoclonal antibodies anti CD20 (Rituximab) was started. The tumor had a complete and prolonged (24 months) remission after the treatment

AB BACKGROUND AND PURPOSE: The GDC system is a valuable therapeutic alternative to surgical treatment of intracranial aneurysms. We present our clinical experience with the GDC technique used to treat unruptured cerebral aneurysms. METHODS: This is a retrospective review of 217

patients with 247 unruptured intracranial aneurysms who underwent embolization with GDCs between August 1991 and June 2000. One hundred sixty-seven of the 217 were female patients. Patient age ranged from 13 to 83 years. In 118 patients, the aneurysms were found when unrelated non-neurologic conditions indicated angiography, CT angiography, or MR angiography (group 1). Fifty-one patients with mass effect symptoms comprised group 2, 12 patients with aneurysms associated with arteriovenous malformations or tumors of the brain comprised group 3, 17 patients with unruptured aneurysms treated during the chronic phase of subarachnoid hemorrhage (SAH) comprised group 4, and 19 patients treated during the acute phase of SAH due to another ruptured aneurysm comprised group 5. RESULTS: Angiographic results revealed complete occlusion in 138 of 247 aneurysms (55.9%), neck remnants in 92 (37.2%), and incomplete occlusion in three (1.2%). GDC embolization was attempted unsuccessfully in 14 aneurysms (5.7%). Of the 198 patients without acute SAH (groups 1-4), 186 (93.9%) of 198 remained neurologically unchanged. Eleven of the 217 patients (5.1%) experienced neurologic deterioration caused by immediate procedural complications. One patient died (0.5%) as a result of aneurysmal rupture during embolization. For asymptomatic patients and those treated after the chronic period of SAH, the mean hospitalization stay was 2.9 days. CONCLUSION. GDC technology constitutes safe treatment for unruptured aneurysms, with successful anatomic and clinical results and low complication rates achieved.

AB The adaptation to the natural environment of the spectacled caiman (*Caiman crocodilus*) raised in captivity and released before the dry season (november-december 1992, 676 individuals) and at the beginning of the rainy season (April-July 1993, 496 individuals) in water bodies of El Cedral ranch, Apure state, Venezuela, was evaluated. The recapture of 210 individuals, between 26 and 523 days after their release, was used to calculate changes in relative fatness, growth rates in their natural habitat, and prevalence of injuries. One hundred and fifteen (115) wild caimans captured in the study area were used as control group. Analyses with a relative fatness index showed that both wild and captive raised caimans lost weight during the dry season, and grew at a very low rate during the dry season, as compared to the growth rate of individuals released at the beginning of the rainy season. Nine out of 78 (11.5%) caimans released with complete tails (16 or more rows in the single crested caudal whorl) lost part of them, presumably due to inter and intraspecific interaction, between three and 17 months after their release. This percentage is lower than the one found in wild caimans of similar sizes, for which 22.8% had lost part of their tail. The results indicated a high adaptability of caimans raised in captivity to the natural environment, and support this procedure as a strategy for the recovery of overexploited or locally extinct populations.

AB The persistence of Trypanosoma cruzi tissue forms was detected in the myocardium of seropositive individuals clinically diagnosed as chronic chagasic patients following endomyocardial biopsies (EMBs) processed by immunohistochemical (peroxidase-anti-peroxidase (PAP) staining) and molecular (polymerase chain reaction (PCR)) techniques. An indirect immunofluorescent technique revealed antigenic deposits in the cardiac tissue in 24 (88.9%) of 27 patients. Persistent T. cruzi amastigotes were detected by PAP staining in the myocardium of 22 (84.6%) of 26 patients. This finding was confirmed with a PCR assay specific for T. cruzi in 21 (91.3%) of 23 biopsy specimens from the same patients. Statistical analysis revealed substantial agreement between PCR and PAP techniques ( $k = 0.68$ ) and the PCR and any serologic test ( $k = 0.77$ ). The histopathologic study of EMB specimens from these patients revealed necrosis, inflammatory infiltrates, and fibrosis, and made it possible to detect heart abnormalities not detected by electrocardiogram and/or cineventriculogram. These indications of myocarditis were supported by the detection of T. cruzi amastigotes by the PAP technique or its genome by PCR. They suggest that although the number of parasites is low in patients with chronic Chagas' disease, their potential for heart damage may be comparable with those present during the acute phase. The urgent necessity for testing new drugs with long-term effects on T. cruzi is discussed in the context of the present results.

Last Updated on STN: 25 May 1999

AB A clinical, parasitologic, and serologic study carried out between 1988 and 1996 on 59 acute-phase patients in areas of western Venezuela where Chagas' disease is endemic showed 19 symptomatic patterns or groups of symptoms appearing in combination with different frequencies. The symptomatic pattern with the highest frequency was that showing simultaneously fever, myalgia, headache, and Romana's sign, which was detected in 20% of the acute-phase patients. Asymptomatic individuals and patients with fever as the only sign of the disease made up 15% and 11.9% of the total acute cases, respectively. Statistical correlation analysis revealed that xenodiagnosis and hemoculture were the most reliable and concordant of the five parasitologic methods used; these two methods also showed the highest proportions in detecting any clinical symptomatic pattern in acute-phase patients. A similar high reliability and concordance was obtained with a direct agglutination test, an indirect immunofluorescent antibody test, and an ELISA as serologic tests, which also showed a higher proportion of positive detection of clinical patterns than parasitologic methods ( $P < 0.001$ ). It is recommended that individuals coming from endemic areas showing mild and/or severe clinical manifestations should be suspected of being in contact or having been in contact with *Trypanosoma cruzi*, be referred for parasitologic and serologic evaluations to confirm the presumptive clinical diagnosis of acute Chagas' disease, and start specific treatment. The epidemiologic implications of the present findings are discussed and the use of similar methodology to evaluate other areas where Chagas' disease is endemic is suggested.

AB By using a PCR assay specific for *Leishmania braziliensis* in blood samples, we detected this parasite in patients cured by immunotherapy or at different stages of treatment. We also found the parasite in subjects who had never suffered leishmaniasis but who had lived in endemic areas and migrated to nonendemic ones many years ago. These results suggest that *L. braziliensis* infections are difficult to eradicate and that a clinical cure but rarely a complete elimination of the parasite is generally accomplished.

 AB The authors designed a PCR assay targeted on repeated element of the  
 ribosomal intergenic spacer which produces highly polymorphic DNA band  
 patterns for different strains of Trypanosoma cruzi. By labeling the PCR  
 products with digoxigenin and by chemiluminescence detection, the authors  
 improved the assay sensitivity by three orders of magnitude to get T.  
 cruzi strain fingerprints in feces of the trypanosome-infected triatomine  
 bug vector. The authors also developed a capture assay for the  
 digoxigenin-labeled PCR products that allowed the authors to detect T.  
 cruzi in triatomine bug vector feces and in human serum samples with a  
 solid support.

AB A prospective epidemiological study was carried out over 1 year to evaluate vitamin B complex dietary intake and status in Cuba, 2 years after the Cuban neuropathy epidemic of 1993. Of the 199 healthy middle-aged men selected, 141 completed the study. Volunteers were followed up every 3 months for 1 year. Dietary intake and status of thiamin, riboflavin, vitamin B(6), folate and vitamin B(12) were assessed each time. The dietary intake of vitamin B complex was low, particularly in June and July (folate), and October (thiamin). A deficient status was observed for vitamin B complex, except for vitamin B(6). Vitamin B complex intake and status varied over the year. However, dietary intake and status were poorly related. The results prove that healthy Cuban men represents a vulnerable population in terms of vitamin B complex status and stress the necessity to both promote preventive multivitamin supplementation and produce local food rich in vitamin B complex.

AB To know the activity of antimeningococcal Ig, Balb/c mice of 18-22 g of body weight were challenged with 5 serotype B strains of Neisseria meningitidis (Nm) isolated from patients of different Latin American countries. The specific antimeningococcal Ig was extracted from the serum of volunteers previously vaccinated with the antimeningococcal BC vaccine VA-MENGOC-BC (Finlay Institute, Havana, Cuba). The Ig was i.p. (IP) administered in a unique dose of 10 mg/mouse. The strains A, B, C, CH and D were inoculated IP in the following charges: strain A, 20 LD50; B, 25 LD50; C, 44.5 LD50; CH, 36 LD50, and D, 200, 20 and 2 LD50. For each strain, a control group received living bacteria and virulent stimulating factor (VSF). The Ig was injected 30 min before or 30 min after the challenge dose had been given, except for strain D, which only received the Ig 30 min after the challenge. As VSF, 0.5 mg of iron in the form of iron dextran was used. The experiment was analyzed considering the survival time after the challenge for each strain compared to the corresponding control group (C). When the Ig was used 30 min before the challenge, the protection period for the A strain was (C:18.1h) more than 72h (P<0.001)

and 100% survival; for the B strain, (C:29.5h) 42h (P<0.05) and almost 20% survival; for the C strain (C:16.5h) 35h (P<0.01) with a 40% survival, and the CH strain (C:18.1h) 26.5h (P<0.02), with a 20% survival. When the Ig was injected 30 min after the challenge, the average survival time and the survival for the A strain was 28h (P<0.05) with 62.5%; for the B strain it was 42 h (P<0.005) and 0.0%; for the C strain 27.3 h (P<0.05) and 30%; for the CH strain 25.8h (P<0.05) and 0.0%, and for the D strain 19.1h, 26h, and more than 72h with a 0.0%, 60% and 100%, depending on the challenging dose. In general, the specific Ig used showed a protective effect in mice against the different Latin American strains tested. Addnl., the exptl. model proved to be useful for the study of the antimeningococcal human Ig.

 LA English  
 AB Glioblastoma (GBM) remains one of the most challenging solid cancers to  
 treat due to its highly proliferative, angiogenic and invasive nature.  
 The small mol. CDK inhibitor, flavopiridol, has demonstrated antitumor  
 activity in human xenograft models and is currently in clin. trials  
 showing efficacy in patients with advanced disease. We have developed an  
 exptl. animal model using the murine glioma GL261 cells as a novel in vivo  
 system to screen potential therapeutic agents for GBM. Results of in  
 vitro testing demonstrate that flavopiridol has several relevant clin.  
 characteristics such as its ability to: (1) inhibit cell growth, (2)

inhibit cell migration, (3) decrease expression of cyclin D1, CDK4 and p21, (4) induce apoptosis in cells with high levels of p27 expression, and (5) decrease the expression of the anti-apoptotic protein Bcl-2. The mechanism by which flavopiridol induces apoptosis is mitochondrial-mediated. We demonstrate by electron microscopy and immunohistochem. that drug treatment induces mitochondrial damage that was accompanied by the release of cytochrome c into the cytosol together with the translocation of apoptosis inducing factor (AIF) into the nucleus. This finding in murine glioma cells differs from the mechanism of flavopiridol-induced cell death reported by us for human glioma cells (Alonso et al., 2003) where drug treatment induced a caspase- and cytochrome c-independent pathway in the absence of detectable damage to mitochondria. In apoptotic human glioma cells only translocation of AIF into the nucleus occurred. Thus, the same drug kills different types of glioma cells by different mitochondrial-dependent pathways.
